The B Ration and the MRE were evaluated for five days during a training exercise at Eglin Air Force Base, Florida, to determine their acceptance and nutritional adequacy in a hot-weather environment. The effects of beverage flavor and beverage variety as well as meal scheduling on consumption were also investigated. The B Ration was consumed for breakfast and dinner and the Meal, Ready-to-Eat was consumed for lunch. The acceptability of each food and beverage item was rate: on a 9-point hedonic scale. A detailed final questionnaire was completed by subjects to determine overall opinions of the rations. Consumption of the B Ration was measured by comparing an estimate of each subject's meal before he began eating to an estimate of each subject's plate waste. Consumption of the MRE was estimated by subjects. The results of the field study indicate that airmen's nutrient and caloric

#19 ABSTRACT (Continued)

intake of the B Ration/MRE did not meet military nutritional standards. The test site allowed access to nonration foods; this probably contributed to reduced intake of the B Ration/MRE. Inadequate energy intake resulted in insufficient consumption of the majority of macronutrients, vitamins and minerals. Of particular concern was the low calcium intake. Flavorants were added to the nonfat reconstituted powdered milk to enhance milk consumption; however, there were no differences in consumption of the flavored versus plain milk. There was some evidence that beverage variety enhanced beverage consumption. Meal scheduling did not affect intake in the present study. The B Ration was well-liked with the exception of certain dairy products and some of the breakfast foods. The MRE V was rated as less acceptable in the present study than in past studies. However, the newly (1988) developed version of the MRE (VIII) has incorporated many of the changes suggested by subjects in the present study. These changes should enhance acceptance and consumption of the MRE in the future.

PREFACE

The authors would like to express their thanks to Ms.

Shirley Townsend for locating the test site and coordinating the test with Detachment 2 of the Air Force Engineering and Services

Center (AFESC) at Eglin Air Force Base, Florida. Sincere thanks are also extended to SMSGT Heyge for coordinating the dining facility staff and functions at Eglin Air Force Base. Special thanks go to Larry Lesher for statistical work, Doris Sherman for work on the nutrient data base, and Irene Abrams for preparing test materials and making preliminary test arrangements with Eglin AFB. Technical work by Joan Kalick, Kathy Rock, Donald Ross, Laurie S. Lester, Barbara Bell, Diane Wisnieski, Larry Lesher and Charles Greene is also greatly appreciated.

INTRODUCTION

The consumption of operational rations in the field in a temperate environment is less than adequate (1, 2, 3). Although the acceptance and nutritional adequacy of the B Ration in an extremely hot environment has not been fully evaluated, one would predict that consumption may not be sufficient to meet the Military Recommended Dietary Allowances (MRDA). The B Ration consists of nonperishable subsistence items (e.g., canned or dehydrated foods) and is used by the Armed Services when hot meals can be served in field dining facilities, but when perishable foods are not yet available or cannot be stored. primary purpose of the field study presented here was to evaluate the nutritional adequacy and acceptance of the B Ration in an extremely hot environment. Another purpose of the field study was to determine the effect of several factors which, in a number of laboratory studies, have been shown to enhance intake. Specifically, the effects of beverage flavor, beverage variety, and scheduled versus nonscheduled mealtimes were all addressed.

Studying the consumption of the B Ration, specifically beverage consumption, in a hot environment is particularly important given that in this type of climate, risk of hypohydration is high. The absence of refrigeration makes it critical that beverages be provided that are palatable when served at ambient temperatures, in order to encourage fluid consumption.

The effect of flavor on drinking behavior in animals and humans is striking (4, 5, 6). Sweetened water can stimulate

drinking in animals that have no hydrational deficit (7, 8, 9), and bitter-flavored water can cause animals to become hypohydrated and even die (10, 11, 12). Although the effect of flavor on fluid consumption has been studied less in humans than in animals, such an effect has been demonstrated. Sohar, Kaly and Adar (13) demonstrated that flavoring water could prevent voluntary dehydration in men during a desert march. Similarly, an Army field test has shown that flavoring can enhance consumption of water in the field (14). In a laboratory study in which a desert environment was simulated, it was shown that both beverage flavor and beverage temperature can affect fluid consumption in men (15).

The effect of serving temperature on the acceptability of several foods and beverages has been investigated in laboratory studies (16, 17). In one study, the effects of serving temperature and flavoring on milk acceptability were investigated (17). Chocolate, strawberry and plain nonfat dry milk were taste-tested at four temperatures. The results indicate that the acceptability of nonfat dry milk increases significantly when flavorants are added; this increase in acceptability holds for a wide range of temperatures.

In addition to the effects of flavor and temperature on beverage consumption, the effects of beverage variety on drinking behavior have also been studied in animals and humans. It has been shown that offering a variety of fluids to rats significantly enhances intake (18). This effect has also been demonstrated in humans in a taste testing situation (18).

Furthermore, it has been shown that beverage variety enhances consumption of B Ration-type beverages <u>and</u> foods in a meal setting (19).

Another factor which may affect food and beverage consumption is meal scheduling. External cues such as the time of day, and the sight, taste, smell and availability of food have been shown to affect eating behavior (20, 21, 22). Humans may eat more when scheduled to eat at a specific time and at a specified location than if they choose to eat whenever and wherever they wish (23).

The field study reported here addressed the question of whether beverage flavor and variety or meal scheduling can enhance consumption of B Ration foods and beverages in an extremely hot environment. Average intake of B Ration foods and beverages was measured to determine whether caloric and nutrient intake was sufficient in meeting the Military Recommended Dietary Allowances (MRDA). Food and beverage acceptability was also measured as was soldiers' satisfaction with factors such as variety and portion size. Additional comments and suggestions were elicited to further evaluate the B Ration in an extreme environment.

METHOD

Subjects

Subjects were 79 airmen (75 men and 4 women) who were participating in a training exercise at Eglin Air Force Base, Florida. Their home base was Mt. Home, Idaho. During the

training exercise at Eglin AFB, most of the men and women worked outside, building or maintaining airstrips. This required moderate to heavy daily physical activity.

Only men were included in the data analysis since so few data points were available for women. Male subjects were an average (± standard error) of 23.4 years of age (± 4.6 months), 70.3 (± 0.32) inches tall (179 cm) and weighed an average of 169.6 (± 2.4) pounds (77 kg). Subjects had been in the Air Force an average of 2.9 years (± 3.5 months).

Procedure

Prior to the study, all subjects were briefed about its purpose. Subjects were told that the B Ration and the Meal, Ready-to-Eat (MRE V) were going to be evaluated for five days during their training exercise. Although other foods were easily accessible, they were asked to limit their diet to the rations and to drink only water and drinks provided at mealtimes during the evaluation period. At the briefing, subjects were divided into eight groups. One representative from the U.S. Army Natick Research, Development and Engineering Center (Natick) was assigned to each group to monitor food and beverage intake during the study. These group leaders explained the study in detail to their respective groups at the briefing. The schedule of the study and the questionnaires that each subject would need to complete were explained. Subjects filled out Background Information and Volunteer Agreement Forms (see Appendices A and B) at that time.

The study was conducted at the dining facility at Eglin Air Force Base. Eglin was chosen by the Air Force as the test site because the Florida weather would be extremely hot in August when the study was to be conducted. Although this location satisfied the requirement for an extreme climate, it should be noted that the field dining conditions at this site were not comparable to those in a battlefield scenario because of the high availability of nonration foods.

The study was conducted for five consecutive days. Three meals per day were evaluated on the first four days; on the last day only breakfast was evaluated. Airmen participating in the evaluation reported to the dining facility 30 minutes prior to the regularly scheduled breakfast and dinner times to minimize interference with those who were not participating in the study. Subjects ate at the same tables every day so that the Natick data collectors could monitor intake for the same group of subjects at each meal. At each breakfast and dinner meal, subjects filled out forms to rate the acceptability of the B Ration.

For lunch, subjects were randomly divided into two groups to determine if meal scheduling affects ration and water intake. Half of the subjects were assigned to the "scheduled group"; this group was required to report to the field dining facility at a designated time to eat their MRE. The other subjects were assigned to the "nonscheduled group"; they could eat their MRE whenever and wherever they wished. Only cold water was available in the dining facility so that water availability would be similar in the two groups. The nonscheduled group could obtain

water from water fountains, which were distributed in a number of locations around the base. All subjects completed consumption and acceptability forms during lunch. These forms were distributed at breakfast and collected at dinner each day.

All B Ration foods and beverages were prepared by experienced cooks and cook trainees according to standard preparation and serving procedures. All ingredients used were recorded by a Natick technician in order to determine if cooks strictly adhered to B Ration recipes. Any deviations from the recipes and cooking procedures were documented so that the nutrient data base could be adjusted to reflect these changes.

Although the majority of items served during the evaluation were B Ration foods, several T Ration items were served as well. The T Ration is similar to the B Ration in that it does not require refrigeration. The T Ration is packaged in a metal container (Tray Pack). Preparation requires only that the Tray Pack be heated; the food is then ready to be served.

At each breakfast and dinner meal, prior to serving the food to the airmen, the cooks prepared 10 food trays to simulate the actual serving of meals on the serving line. Data collectors weighed each food item on the 10 trays to determine the variability in actual serving sizes of B Ration portions. Six "standard trays" were then made up; each tray contained an average-sized portion of each menu item. The trays were then strategically placed on the dining tables to be used by data collectors during the meal. The data collectors compared each

subject's tray to the standard tray to estimate the portion size of each menu item before the subject began eating.

Plate waste was also estimated at breakfast and dinner. The data collectors estimated portions of all foods and beverages after the meal, again, by comparing each subject's tray to the standard tray (i.e., plate waste estimation). After the breakfast and dinner meals, actual plate waste was measured for 25% of the trays. All measurements were made on electronic scales (accuracy ± 1g). Actual plate waste was measured to validate data collectors' estimations.

The breakfast and dinner menus served on the five testing days can be found in Appendix C. In order to investigate the effect of milk flavorants on the acceptance and intake of nonfat dry milk, different flavors were served each day. On some of the testing days, chocolate and strawberry flavorants (Nestle's) were added to the nonfat dry milk that was served at breakfast; either plain, chocolate or strawberry milk was served on three of the days, and all three types of milk were served on two of the days. The flavor(s) served on a given day were randomly assigned.

At the dinner meal, the effect of beverage variety on intake was investigated. Either grape, lemonade or cherry-flavored drink was served at each evening meal, and on one day, all three flavors were served. Again, the flavor(s) served on a given day were randomly assigned. Beverage temperature was measured at each meal. These measurements were recorded because of the known effects of beverage temperature on intake (15) and acceptability (16) in humans.

A nutrient data base was set up for the B Ration by compiling a list of nutrients for all ingredients in recipes served during the five breakfasts and four dinners during the study. Retention/loss factors were included in the data base to compensate for any losses of nutrients (predominantly vitamins) that occur during cooking. Other factors such as evaporation of moisture and the addition of fat during cooking were also accounted for in the data base to allow for a more accurate measure of nutrient intake. Nutrient data for the T Ration was provided by the Food Engineering Directorate at Natick and was also included in the data base. Nutrient and caloric intake for breakfast and dinner were calculated from information in this data base and B Ration/T Ration consumption data. An MRE nutrient data base (which was comprised of nutrient information for MRE V provided by the Food Engineering Directorate) and MRE consumption data were used to compute nutrient and caloric intake of the MRE.

Data Collection

B Ration and MRE acceptability forms (Appendices D and E) were used to collect acceptability data. A 9-point hedonic scale was used to rate the acceptability of each food and beverage item, where 1 corresponds to "dislike extremely," 5 corresponds to "neither like nor dislike," and 9 corresponds to "like extremely" (24).

B Ration and MRE intake forms (Appendices F and E) were used to collect intake data for each 24-hour period. Intake of the B

Ration was measured by data collectors, who estimated portions of each food and beverage served to each subject before and after the breakfast and dinner meals. Pre- and postmeal estimations were recorded on the B Ration intake form. Intake at lunch was recorded on the MRE intake form by subjects who estimated the portion of each item they consumed, i.e., 1 portion, 1/2, 1/4, 0, etc. This form was also used to record any food or drinks consumed between meals.

Prior to the field study, data collectors were trained in estimating portion sizes of a variety of B Ration-type and T Ration foods and beverages. At the end of the five-day training, a linear regression analysis was done to determine the relationship between data collectors' estimates and actual portion sizes. The resulting regression equation for estimates of the food items ($y = B_0 + B_1 x$, where y =estimate and x =actual) was y = .031 + (.909 * x), $R^2 = 0.854$. An exact relationship would exist when $B_0 = 0$ and $B_1 = 1$. The equation for beverage estimates was y = .023 + (.989 * x), $R^2 = 0.972$. From these results, it can be concluded that data collectors' estimates were closely related to actual portion sizes. Beverage estimates were even more closely related than food estimates.

A final questionnaire (see Appendix G) was used to determine overall opinions about the B Ration and the MRE. Overall acceptability of each item was rated on the 9-point hedonic scale described above. Satisfaction with other characteristics of the ration was measured on a 7-point scale, where 1 corresponds to "very dissatisfied" and 7 corresponds to "very satisfied."

Portion size of the different components of each ration was rated on a 7-point scale, where I corresponds to "portion much too small" and 7 corresponds to "portion much too large." Opinions about the variety of the ration, feelings of hunger and thirst, as well as other issues concerning the consumption of the B Ration and the MRE in a hot environment were also measured on the final questionnaire.

RESULTS AND DISCUSSION

Average Daily Intake

To determine if intake of the rations was sufficient to meet military nutritional standards, average daily consumption was calculated. These results are summarized in Table 1. Military Recommended Dietary Allowances (MRDA) for an operational ration (e.g., B Ration, T Ration and MRE) are listed in Table 2. By comparing intake with the MRDA, it is apparent that consumption of the operational ration during the four-day evaluation period did not sufficiently meet military nutritional standards, with the exception of intakes of vitamin D, ascorpic acid, phosphorus, and potassium. Results of t-tests revealed that average consumption of all other nutrients as well as energy was significantly lower (p<.001) than the MRDA. Figures 1-5 illustrate daily consumption of carbohydrate, protein, fat, sodium and calories compared to the MRDA. Mean caloric intake was 2200 kcal, which is only 61% of the MRDA. Average intake from the rations ranged from 589~4365 kcal. Only four subjects

consumed at least 3600 kcal/day, which is the MRDA for energy. For a number of vitamins and minerals (e.g., calcium, magnesium, riboflavin, vitamin A, vitamin B-6) intake was similarly low. It must be noted that there were missing values for certain nutrients for some foods and beverages in the data base; means should be viewed as minimum values, particularly for those nutrients that were not included at all in the MRE data base (see Table 1).

Consumption of certain nutrients, such as sodium, fat and cholesterol, should be kept to a minimum. The average intake of cholesterol was 390 mg (see Figure 6), significantly higher than the 300 mg limit recommended by the American Heart Association. The majority of cholesterol was consumed from the B Ration at breakfast (see Figure 7). Reducing the frequency of serving eggs at breakfast would help to lower overall intake of dietary cholesterol.

The limited intake of calcium was related to the minimal consumption of milk products; for the most part, milk and cottage cheese. These items received low acceptability ratings. In order to make up for the lack in calcium intake, it may be necessary to increase the frequency of serving other B Ration foods high in calcium, which may be more acceptable, such as American cheese. However, there are very few other B Ration foods rich in calcium. It may be desirable to add other foods to the B Ration, which contain significant amounts of calcium. Cheese pizza, which is generally a well-liked item, is a food which could be added, given the ingredients currently available

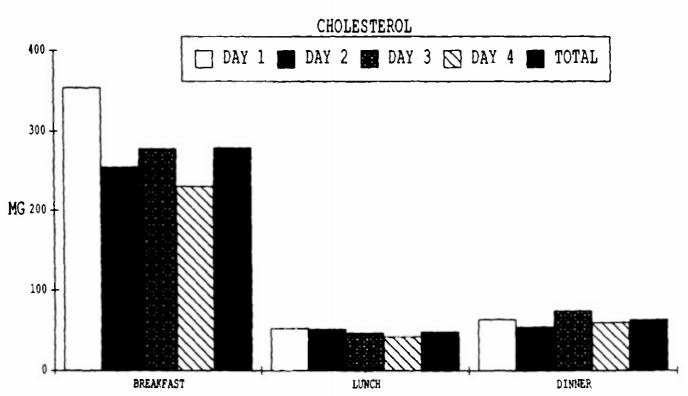

Figure 7. Average Cholesterol Intake at Each Meal During the 4 Day Period.

as part of the B Ration. An alternate solution would be to fortify other B Ration foods with calcium. It would also be possible to substitute T Ration lasagna for one of the B Ration entrees.

Airmen did not eat enough food, as was evidenced by the low daily intake of energy. Although increasing the consumption of certain foods and beverages would increase the intake of specific nutrients, increasing the <u>total</u> amount of ration foods consumed would significantly reduce the gap between intake and the MRDA of the majority of nutrients and energy.

Average Intake at Breakfast, Lunch and Dinner

To determine if the overall low energy intake was the result of low intake of a particular meal or ration, intake was analyzed separately by meal. These results can be found in Tables 3 - 5.

Tables 3 and 4 summarize the results of nutrient and caloric intake of the B Ration/T Ration at breakfast and dinner during the four-day evaluation period. (The intake data from breakfast on Day 5 were not included in the analysis because most subjects did not eat breakfast on the last day.) Table 5 summarizes nutrient and caloric intake of the MRE. Average intake of the B Ration at breakfast and dinner was 823 kcal and 863 kcal, respectively. Average intake at lunch was only 518 kcal. These results indicate that average intake of the MRE (V) was significantly lower than that of the B Ration.

In other MRE field studies in which the MRE (IV) was consumed for three meals per day, between 60 and 68% of the available calories in the MRE were consumed (1, 2). (The only

^{*} Water consumed from the food and beverages.

difference between MRE IV and MRE V is the date of issue.) In a previous study in which the 'two B Ration/one MRE' schedule was used (3), 708 (58%) of the available kcal were consumed from the MRE. In the present study, subjects ate an average of only 43% of the available calories in one MRE. One explanation for the limited intake is that the acceptability ratings for some of the MRE foods were low, particularly for a number of the entrees. Average ratings of acceptability for individual MRE items can be found in Table 6; acceptability ratings by food group are summarized in Table 7. The majority of foods received ratings of '6' ("like slightly") or less. In past studies (1, 2), acceptability ratings of the MRE were notably higher.

Subjects may have consumed small amounts of food during lunchtime as well as at other times of the day because of the extreme heat and humidity. Temperature in the dining facility as well as atmospheric temperature and humidity levels were measured on a regular basis during the study (see Appendix H). The average temperature in the dining tent during breakfast hours was 77.7°F (25.4°C), during lunchtime, 89.8°F (32.1°C), and during dinner hours, 92.4°F (33.6°C). The average temperature in the field during the five days was 84.1°F (28.9°C). The average relative humidity in the field was 73%. The high temperatures, in combination with the high levels of humidity during the study indicate that the climate was extremely hot; the Wet Bulb Global Temperature (WBGT Index) was 85-87°F during several hours of each day, indicating risk of heat stress.

In addition to intake being low at lunchtime, intake at the dinner meal was also significantly less than in previous studies. For example, in an Army study in which the two 'B Ration/one MRE' schedule was used (3), average intake of the B Ration at dinner was 1234 kcal, compared to 863 kcal in the present study. As will be discussed later in this report, the B Ration was well-liked overall. With the exception of several of the entrees and vegetables, the items liked the least were items served during breakfast. Therefore, the acceptability of the ration does not seem to explain the comparatively low intake at dinner in the present study.

An alternate explanation for the limited consumption of the B Ration at dinner is that a number of sources of nonration foods were available to the airmen. Although participants were asked to refrain from eating any nonration food, it was apparent that

they did consume other foods and beverages, which they brought with them or which they obtained from vending machines and other sources. Subjects were asked to write down any foods and beverages they consumed between meals on their intake forms.

Although some subjects ate leftover foods from their MRE between meals, the majority of items listed consisted of nonration foods such as pizza, chips, nuts, cookies, candy and soda. Most of these foods were consumed in the afternoon before dinner or in the evening.

In past field studies (1, 2, 3), which were conducted in more isolated sites, nonration foods were not available. Without the consumption of these additional foods in the present study, the overall average daily intake of the rations, and particularly intake of the dinner meal, might very possibly have been higher.

The consumption of nonration items has further implications for the results of the present study. Only data from consumption of rations during meals are included in the preceding graphs and tables. From the information reported by subjects on their consumption forms, it was determined that some airmen ate between 1000 and 2000 additional calories between meals. Since the protocol required consumption of the B Ration and MRE only, it is also possible that much of the nonration foods eaten during the evaluation was not reported. For these reasons, some subjects may, in fact, have consumed the MRDA for energy and perhaps some nutrients. However, many of these subjects were probably still deficient in a number of vitamins and minerals, since the

majority of the nonration items consumed were foods and beverages consisting mainly of "empty" calories.

Beverage Intake

Beverage intake was estimated by data collectors at breakfast and dinner. Beverages available at breakfast included water, coffee, juice, and milk. Beverages served at dinner included water, coffee, and flavored beverages. (Appendix C lists the beverages served on each day.) Average total beverage intake at breakfast and dinner are summarized in Table 8. The only beverages available during lunch were coffee, cocoa and water. Because of the hot weather, and because no means was available to heat water, intake of coffee and cocoa was very low at lunch. Less than 10% of subjects drank either of these beverages at lunch. Subjects estimated their intake of water on their consumption forms. However, most subjects did not distinguish between water intake "during" and "between" meals. Therefore, water intake during lunch could not be accurately determined. Water intake during lunch and between meals is reported in the following section.

Possibly because of the lack of beverages available in the MRE, over 60% of the subjects reported that they drank at least one can of soda (e.g., Coca Cola, Sprite) each day. Several subjects had as many as 7-11 cans of soda per day. The average daily consumption of soda was 24.9 ounces, cr approximately two cans of soda per day. These results emphasize the need to include a greater variety of beverages in the MRE, particularly

TABLE 8.

Average Beverage Consumption at Breakfast and Dinner.

Day	Breakfast (g)	Dinner (g)
1	418	496
2	424	543
3	475	651
4	476	611
Average	448	576

for consumption in hot-weather environments. The most recent procurements of the MRE (VII and VIII) include flavored beverage powders. This should enhance beverage consumption in future field studies, and may possibly reduce the consumption of nonration beverages (if they are available) in the field.

Water Intake Between Meals

In addition to estimating food and beverage consumption, subjects also estimated how much water they drank at lunch and between meals on their consumption forms. On Day 1, subjects estimated, on average, that they drank about one canteen of water at lunch and between meals. Only about 32% reported drinking water at lunch or between meals on this day. Since this was the first day of the study, they were not familiar with filling out the questionnaires; consequently, this may not be a true estimate of water intake during lunch and between meals for Day 1. On Day 2, airmen consumed an average of two and one half canteens of water at lunch or between meals. On Day 3, the mean was

approximately three canteens. The average water intake on Day 4 was about four and one half canteens.

In a previous Army study (1), the average amount of drinking water consumed per day in three different MRE groups (MRE IV, VII, VIII) was 3014 mL, 2502 mL, and 2610 mL, respectively. In another study (2), the MRE group drank 2383 mL, and the 'two A Ration/one MRE' group drank 1462 mL of water per day. In the present study, subjects drank an average of approximately 2950 mL of water at lunch and between meals. This amount, added to the 1000+ mL of additional fluid consumed, on average, at breakfast and dinner, seems to exceed overall water intake from plain drinking water and other beverages in comparison to past studies. However, additional fluid was needed because of the extreme hot and humid environment and the moderate to high activity level maintained during the day.

When subjects were asked to describe their level of physical activity during the week of the study, 43% said they engaged in heavy daily physical activity, 37% engaged in moderate physical activity, 9% in light physical activity, and 11% said their activity level was mixed.

When asked about their overall feelings of thirst during the study, 46% felt they got enough to drink, 28% were sometimes thirsty, 20% were often thirsty, while 7% responded that they were thirsty almost all of the time. Even though average fluid intake during the study seems sufficient, for about 27% of the airmen, thirst was a problem. The addition of flavored beverage powders to the MRE should alleviate this problem.

Effect of Beverage Variety on Beverage Consumption

The effect of beverage variety on beverage intake was investigated during the dinner meal. On Days 1, 2, and 4, only one flavored beverage was served at dinner, either cherry, grape or lemonade (the no variety condition). On Day 3, all three flavors were served (the variety condition). Both water and coffee were also available at each meal. Total beverage intake per meal was calculated. Total beverage intake at dinner (this includes intake of the flavored beverages as well as water and coffee) was 496 g, 543 g, 651 g, and 611 g, on Days 1-4, respectively (see Table 8, p. 27). Table 9 shows total intake of just the flavored beverages during the dinner meal. Analysis of variance revealed a significant difference (p<.001) in total beverage intake and in intake of the flavored beverages among the four days. A post-hoc Student-Newman-Keuls test found that intake on Day 3 (variety) was significantly different (p<.05) than intake on Days 1 (cherry) and 2 (grape); it was not significantly different from intake on Day 4 when lemonade was served. Consumption of beverages on Days 1 and 4 was also significantly different (p<.05).

That intake did not differ on Days 3 (variety) and 4 (lemonade only) may be explained by the fact that the serving temperature of lemonade, for some unknown reason, was lower than the serving temperatures of the other beverages (lemonade - 46°F (8°C), cherry - 69°F (21°C), and grape - 64°F (18°C)). In past studies (16, 17), the preferred temperature of flavored beverages was found to be 40°F (4°C). The cooler temperature of the

lemonade may account for higher intake on day 4 than on the other "no variety" days.

TABLE 9.

Mean Acceptability Ratings and Intake of Flavored Beverages
During the Dinner Meal.

4	Lemonade	574	7.31

^{* 1 =} Dislike Extremely ... 9 = Like Extremely

There appears to be some evidence that beverage intake was highest on Day 3 because of the increased variety of beverages available. However, other factors may have also contributed to increased beverage consumption on that day. For example, although an attempt was made to serve equally palatable foods at each meal, on Day 3, the entrees received very high acceptability ratings (see Table 10, p. 35). The high acceptability ratings of the entrees served on Day 3 may have contributed to greater acceptability of the flavored beverages on that day than on the other days (see Table 9), and subsequently, increased consumption. Past research has shown that acceptability of the entree has a significant effect on the acceptability of the rest of the meal (25). In addition, the high acceptability ratings of the entrees may have contributed to greater consumption of food

during the meal, which subsequently may have resulted in greater beverage intake.

Because many variables that may have contributed to the increased beverage intake on the variety day could not be held constant, such as the acceptability of the entrees served on each day, the subjects' preferences for the various beverages, temperature and humidity on each day, and subjects' activity levels, it is difficult to conclude which factors were responsible for the increased intake. However, laboratory research has indicated a relationship between beverage variety and intake. The results of this study also suggest that beverage variety may enhance beverage consumption.

Effect of Flavorants on the Acceptance and Consumption of Milk

Adding flavorants to the warm milk (the average serving temperature of the milk was 65°F (18°C)) did not have a positive effect on acceptability and did not enhance milk consumption. The milk was given extremely low ratings. On Day 1, plain milk was served with breakfast; only 24 subjects tasted the milk, and these subjects rated it poorly. This is consistent with acceptability data of plain, nonfat dry milk collected in a taste-testing study and served at a comparable temperature (17). On Day 2, only 14 airmen (18% of the subjects) tasted the chocolate-flavored nonfat dry milk. It, too, received low acceptability ratings. On subsequent days, 8 or fewer subjects (10% of the total) selected milk to drink at breakfast.

Although the acceptability data for the flavored milk is inconsistent with the laboratory data which showed that adding flavorants to warm milk increases its acceptability (17), the small number of subjects does not allow valid comparisons to be made. In future studies of food acceptability in a cafeteria-style setting, the protocol should encourage all subjects to at least taste all foods and beverages that are being evaluated.

Another factor which could be investigated in future studies is the effect of ambient temperature as well as beverage temperature on beverage acceptability. The temperature in the dining facility may have contributed to the low acceptability ratings of the milk (the average ambient temperature during breakfast was 77.7°F, 25.4°C). Previous studies were conducted in a laboratory setting at room temperature (16, 17).

Effect of Meal Scheduling on Intake of the MRE

An analysis of variance was done to determine if there were any differences in intake between the scheduled and nonscheduled lunch groups. No significant differences were found for intake of calories, water, protein, fat or carbohydrate. Therefore the data were collapsed across conditions to compute the average intake of the MRE reported in Table 5.

The finding that meal scheduling did not affect intake supports research done by Schacter (23) in which college students' intake of dinner was compared during weekdays (presumably scheduled) and weekends (presumably less scheduled).

He found that subjects ate dinner just as frequently at either time of the week. Schacter postulates that people of normal weight seem to be influenced by internal cues of hunger rather than by external cues such as meal schedules. This phenomenon may explain the results of the present study.

Validation of Consumption Estimates

Consumption of the B Ration was measured by the visual estimation or plate waste visual assessment method (26, 27). evaluate the accuracy of this method in the present study, a multiple regression analysis was done to determine the agreement between data collectors' estimates of plate waste and actual plate waste. For estimations of food, the resulting regression equation $(y = B_0 + B_1x)$, where y = estimate and x = actual) was y = constant0.060 + (0.80 * x), $R^2 = 0.80$. An exact relationship would exist when $B_0 = 0$, and $B_1 = 1$. When estimating plate waste of food, when 0.3 or less of the portion was leftover, data collectors tended to slightly overestimate, within 6% of the actual value. When more than 0.3 of the portion was leftover, data collectors tended to underestimate plate waste. From 0.3 to 0.6 of a portion, underestimations were within 6% of actual values; when more than 0.6 of a portion was leftover, estimates were somewhat less accurate, but within 14% of actuals. In general, estimates of food correlated well with actual values. For beverages, data collectors' estimates and actual measurements were almost exactly the same $(y = 0.001 + 1.01x, R^2 = 0.98)$. These results indicate

that the method used during this study was an efficient and valid method of measuring food consumption.

Acceptability of the B Ration

Mean acceptability ratings of the B Ration/T Ration are provided in Table 10. The ration was generally well-liked with the exception of some of the breakfast items and the dairy products. The B Ration foods that were liked the most were creole shrimp, creole chicken, bread (this was a store-bought item), fruit cocktail, pineapple, water, lemonade, cherry-flavored beverage, peanut butter and jelly. The T Ration foods that were well-liked were pepper steak with sauce and peas with mushrooms. The B Ration foods disliked the most were the grilled breakfast meat, scrambled eggs, hash brown potatoes, cottage cheese, peaches, and the milks, both plain and flavored. Acceptability ratings of the B Ration/T Ration by food group are shown in Table 11.

The flavored beverages received high acceptability ratings even though the temperatures at which they were served were fairly high, with the exception of lemonade (lemonade - 46°F (8°C), cherry - 69°F (21°C), and grape - 64°F (18°C)). In past studies (16, 17), the preferred temperature of flavored beverages was found to be 40°F (4°C). No ice was available to add to the drinks. Water received even higher ratings; however, the water was cold because it was dispensed from a water fountain. The milk, as discussed previously, was not well-accepted, although only a small number of subjects actually tasted it.

Overall Opinions of the B Ration and MRE Elicited from the Final Ouestionnaire

The final questionnaire used in this study (see Appendix G) was very similar to the final questionnaire used to evaluate the MRE in other field studies conducted in 1983 and 1986 (1, 2). When applicable, the results of the present study will be compared to these studies. In the present study, MRE V was used; in the 1983 and 1986 studies (1, 2), MRE IV was used. However, the only difference between MRE IV and V is the date of issue; the formulation and components of the ration are the same.

Subjects were asked to rate the overall acceptability of each B Ration item and each MRE item that was served during the five days of the study. Mean acceptability ratings for the B Ration and MRE are summarized in Tables 12 and 13, respectively.

In the 1983 Army study (3), the B Ration was also evaluated. The acceptance of individual food items at the dinner meal was rated by subjects. Most items received neutral ratings or were disliked slightly in the 1983 study, while almost all items were liked in the present study.

It should be noted that the B Ration used by the Army is slightly different than the Air Force's B Ration. In addition, new versions of the ration were issued by both the Army and the Air Force in 1984. Given this information, it is interesting that subjects in the present study ate less at the dinner meal than in the previous study (863 kcal versus 1234 kcal), even though they liked the B Ration better. This lends further credence to the idea that airmen ate less because they had access

to alternate food sources and were consuming other foods in addition to the ration.

In general, the MRE was given lower acceptability ratings in the present study than in previous evaluations. There are several possible explanations for these differences. As was mentioned previously, the only food available for the experimental group in the 1983 (a 34-day test) and 1986 (an 11-day test) field studies was the MRE. In the present study, the B Ration and nonration foods were consumed. Perhaps the MRE is more acceptable if there is no alternative, particularly for long periods of time. The two previous studies were conducted at more isolated sites where other sources of food were unavailable. The previous tests were also conducted in a temperate climate; the MRE may be more acceptable in a temperate climate than in a hot climate.

Paired t-tests were done to determine if field test acceptability ratings of the B Ration and MRE were similar to posttest ratings (from the final questionnaire). Only subjects who had rated foods at both of these times were included in this

analysis. It was found that a number of food items were rated significantly higher during the test than after the test, i.e., foods were given higher acceptability ratings while they were being eaten than when they were rated at a time when the foods were not present. Similar results have been obtained in the past (1).

The difference between during-the-field-test and posttest acceptability ratings may be explained by a number of psychological mechanisms. One possible explanation could involve the general perception of operational rations. When subjects were given the list of foods to rate on acceptability on the final questionnaire, they may have tended to give the foods low ratings because of an overall negative perception of operational rations, or because they were using nonration food as a frame of reference. But when the foods were rated during meals at the same time at which they were eaten (i.e., during the field test), they were rated more positively. This may reflect some rationalization (i.e., "If I am eating this, then it must be good."). The few foods that were rated slightly higher on the final questionnaire than during the test, were foods that are typically viewed as "tasting good."

The final questionnaire asked airmen about overall hunger during the week of the study. Thirty-three percent of the subjects responded that they had enough to eat during the week, while 42% felt hungry some of the time, and 24% were often hungry. One possible explanation for feeling hungry could be

that airmen were not served sufficient quantities of food. The issue of portion size was addressed on the final questionnaire.

The majority of respondents felt the portions of both rations were either just right or too small. They were more satisfied with portion size in the B Ration than the MRE. In the previous field studies (1,2), soldiers also found the MRE portion sizes to be somewhat small. The most recent procurement of the MRE (MRE VIII) includes larger portions of entrees (8 oz. vs. 5 oz.). The mean ratings for portion size can be found in Table 14.

TABLE 14.

SPREADS	3.7	3.2

* 1 = Portion Size Much Too Small ... 7 = Portion Size Much Too Large

In general, the airmen's ratings of portion size do not seem to explain the hunger they experienced during the evaluation. Given their low average energy intake (see Table 1), it is no surprise that they felt hungry at times during the study. Rather than not having enough to eat, it seems clear that many subjects did not consume all that was served to them, especially for lunch (the MRE). The reasons that they did not eat enough can be partially explained by the low acceptability ratings of some of

the foods served during the evaluation period. In addition to several reasons already expounded upon, the responses to some of the other questions on the final questionnaire may also explain the limited food intake.

Subjects were asked to rate their satisfaction with various aspects of the B Ration on a 7-point scale. Fifty-three percent of the subjects were satisfied (i.e., ratings greater than '4') with the flavor of the B Ration, 60% were satisfied with its appearance, 67% were satisfied with the amount of food in the B Ration, 51% were satisfied with the amount of variety between meals, and 59% were satisfied with the nutritional value of the ration.

Satisfaction with these factors of the MRE was rated on the same 7-point scale. Subjects responded with significantly lower ratings for the MRE: only 19% were satisfied with the flavor of the MRE, 12% with its appearance, 26% with the amount of food in the ration, 26% with variety between meals, and 27% with its nutritional value. The means for each factor are summarized in Table 15.

TABLE 15.

Mean Satisfaction Ratings, B Ration and MRE. *

<u>B</u>	RATION	MRE
FLAVOR OF FOOD	4.3	3.1
APPEARANCE OF FOOD	4.6	2.8
AMOUNT OF FOOD	4.8	3.2
VARIETY BETWEEN MEALS	4.3	3.4
NUTRITIONAL VALUE OF MEALS	4.8	3.7

^{* 1 =} Very Dissatisfied ... 4 = Neutral ... 7 = Very Satisfied

In the 1986 field study (1), similar results were obtained. However, in the 1983 study (2), satisfaction with flavor, appearance and variety was greater than in the present study, but there was less satisfaction with the amount of food in the MRE in 1983 than in the present test. Because the 1983 study was a longer test and there was no alternative food choice, subjects may have rationalized that since they ate the MRE for 34 days, they must have been satisfied with it. Similarly, subjects in the 1983 study may have been somewhat more dissatisfied with the amount of food in the ration because the MRE was their sole source of food for such a long period of time.

Subjects were asked to rate how often they heated the MRE entree. The scale ranged from 1 (never) to 6 (always). Eighty-seven percent of subjects said they never heated the MRE. Dissatisfaction and limited intake of the MRE may have been a consequence of having to eat the MRE entrees cold. Although some subjects may have not wanted to eat hot food because of the hot weather, it appears that most individuals prefer to eat foods at normal serving temperatures. Appropriate serving temperature is important to acceptance (16).

Satisfaction with the variety of each food group was rated for the B Ration and the MRE. Variety was rated on a 4-point scale, where 1 corresponds to "variety now enough," and 4 corresponds to "should be much more variety." Mean ratings of variety for the B Ration and MRE can be found in Table 16. Similar ratings of variety for the MRE were obtained in the previous field studies (1, 2). Table 16 also includes the

percentages of subjects who felt that the rations contained enough variety.

TABLE 16.

^{* 1 =} Variety Now Enough ... 4 = Should Be Much More Variety

When asked which food items they would like added to the B Ration, condiments were listed by 36% of subjects. The ones mentioned the most were catsup (14%) and butter (9%). Mustard, Tabasco (R) sauce, steak sauce, gravy and spices were also mentioned. Catsup, mustard and various spices are already included in the B Ration; they may not have been available during the present evaluation. Drinks, particularly cold drinks, such as soft drinks, Gatorade (R) and milk were popular requests. Spaghetti, candy bars and more fruit were also mentioned.

When asked what they would like added to the ration when it was to be eaten in hot environments, 14% of subjects mentioned that they would like to have more of a variety of drinks, especially cold drinks such as soft drinks, flavored drinks, iced tea, cold water and Gatorade (R). They would also like to have

ice. A number of subjects suggested having cold sandwiches rather than hot meals at dinnertime.

When asked which B Ration items they would like dropped, milk was listed by 13 subjects (eight who had tried the milk during the evaluation period, five who had not). If the milk were dropped, the calcium content of the ration would be greatly reduced. A number of subjects also mentioned that eggs, hash browns, grilled meat and succotash should be dropped.

Particularly in hot environments, milk was again mentioned as an item which should be dropped from the menu. As was noted previously, a large number of subjects did not even taste the milk. Subjects also did not indicate which flavor milk they felt should be deleted from the ration; it is not clear whether they were referring to the plain, chocolate or strawberry milk, or milk in general. Since the warm, nonfat reconstituted milk is clearly not acceptable, its recipe should be reformulated.

Otherwise, additional sources of calcium need to be considered.

The final questionnaire also addressed subjects' general opinions and preferences related to eating in a hot environment. Subjects either agreed or disagreed with several statements using a 7-point scale, where 1 corresponds to "disagree extremely," 4 corresponds to "neither agree nor disagree," and 7 corresponds to "agree extremely." In response to a statement about preference for eating more salty foods in hot versus cold weather, subjects stated a very slight preference for liking more salty foods in a hot versus a cold environment ($\bar{x} = 4.4$, SD = 1.6). Subjects agreed that they drink more beverages when the weather is hot

than when it is cold (\bar{x} = 6.3, SD = 1.4). There was generally slight agreement with the statements "I like to eat less when the weather is hot than when it is cool." and "I like to eat more cold foods when the weather is hot than when it is cool." (\bar{x} = 5.2, SD = 1.7; \bar{x} = 4.8, SD = 1.7, respectively). Most subjects did not like to eat spicier foods during hot weather than during cold weather (\bar{x} = 3.2, SD = 1.5).

Subjects were asked to list any foods or beverages they consumed more or less of during the week of the study because of the heat. Ninety-two percent of subjects said they drank more beverages during the week; 83% drank more water, 43% drank more soft drinks (which were obtained from vending machines), and 9% drank more of other beverages such as fruit-flavored drinks. Subjects reported that they drank less milk and hot beverages during the week and ate less meat and less food in general. Because they were asked to restrict their diet to the B Ration and MRE items, those that abided by the restrictions also drank less soda and ate fewer fresh foods than usual.

When asked to comment on the MRE overall, about one quarter of the subjects said they didn't like them. A number of subjects mentioned that although the ration was adequate for its purpose, it needed improvement, e.g., more variety, better taste, and larger portions. These changes have been implemented in the newly developed MRE VIII. Other subjects mentioned that the dehydrated items would taste much better if hot water were available to add to them.

About 12% commented positively about the B Ration, saying that it was better than expected or it tasted good. A number of subjects felt it generally needed improvement; some specific improvements included making the breakfast better and improving the quality of certain items, in particular, the milk and the eggs. Others commented that the day-to-day cooking was variable; some days it was good, and other days it was poor. In fact, meals were not prepared by the same cooks each day. Additional suggestions included adding more drinks and fruit to the ration, and decreasing the amount of hot food served in hot environments.

CONCLUSIONS AND RECOMMENDATIONS

The results of the present study suggest that the airmen's consumption of the B Ration and MRE in an extremely hot environment does not meet military requirements. Intake of the majority of vitamins, minerals and macronutrients was below the MRDA because average energy intake was only 2200 kilocalories. The low intake of vitamin A and calcium is of particular concern. Serving more vegetables containing large amounts of vitamin A such as broccoli, carrots and spinach is recommended. The low calcium intake is largely the result of dissatisfaction with the milk and cottage cheese. Additional foods rich in calcium need to be added to the B Ration. One possibility that would help to increase calcium intake would be to formulate a recipe for cheese pizza as part of the B Ration. Since pizza was a nonration item

reportedly consumed by airmen during the study, it would probably be a welcome addition to the ration. Another possibility would be to substitute T Ration lasagna for one of the regular B Ration entrees. An alternate solution would be to fortify B Ration foods with calcium. Presently, the hot cocoa is fortified with calcium; however, this would not be an item that would be served in hot environments.

Eglin Air Force Base cannot be considered a typical field site because of the wide availability of nonration foods. If the operational ration was the only source of food available, it is possible that ration consumption and nutrient intake would have been higher, especially at the dinner meal. The data show that airmen at Eglin ate a considerable amount of nonration foods. Studies should be done in more isolated sites to determine actual consumption of the B Ration in a field environment.

Even though there were nonration foods available, the B Ration was well accepted, with the exception of the dairy products and some of the breakfast foods. Given that the cholesterol intake was high at breakfast and the acceptability of the eggs was low, it is recommended that eggs be served less frequently. An egg substitute could also be used in recipes to reduce the intake of cholesterol.

There was no evidence from the results of this study that adding flavorants to the currently available dehydrated milk increased its acceptability or enhanced consumption at warm temperatures. The extremely low acceptability ratings of the milk reported in this evaluation suggest a need to reformulate

this B Ration item. In fact, there is currently (FY88) a project being conducted by the Food Engineering Directorate at Natick to reformulate the dehydrated milk base.

Acceptability and satisfaction ratings of the MRE were significantly lower than ratings of the B Ration. Problems with the MRE mentioned by airmen in the present study have been addressed by food developers. The most recent procurement of the MRE (MRE VIII) includes larger entree portion sizes, new and reformulated entrees, fruit-flavored beverage powders, commercial candy, and hot sauce. The dehydrated meat patties received very low ratings in the present evaluation and these have been removed from MRE VIII. These improvements have increased the acceptance and consumption of the MRE (1).

Recommendations for improving the B Ration, particularly when the ration is to be consumed in hot environments, include increasing the variety of beverages, serving cold sandwiches at dinner rather than hot meals, and adding more condiments to the ration. Menu modifications are also suggested to improve calcium and vitamin A intake. Since refrigeration is not available, it is especially important that beverages be served which are acceptable when served at room temperature.

APPENDIX B. VOLUNTEER AGREEMENT FORM

VOLUNTEER AGREEMENT AFFIDAVIT

For you of this form, see AR 46-38; the proponent agency is the Office of the Surgeon Bonoral

THIS FORM IS AFFECTED BY THE PRIVACY ACT OF 1974

- 1. AUTHORITY: 10 USC 3012, 44 USC 3101 and 10 USC 1071-1087.
- 2. PRINCIPAL PURPOSE: To document voluctary participation in the Citoical Investigation and Research Program. SSN and home address will be used for identification and locating purpose.
- 3. ROUTINE USES: The SSN end home eddress will be used for identification and locating purposes. Information derived from the study will be used to document the etudy; implementation of medical programs, teaching; edjudication of claims; and for the mandatory reporting of medical condition as required by law. Information may be furnished to Federal, State and local agencies.
- 4. MANDATORY OR VOLUNTARY DISCLOSURE: The furnishing of SSN and home address is me odatory and necessary to provide identification and to contact you if future information indicates that your health may be adversely affected. Fallure to provide the information may preclude your voluntary participation in this incestigational study.

VOLUNTEER'S EXPLANATION

The purpose of this study is to evaluate the ecceptability of B-retions in a hot environment.

The etudy will take place at breakfest, lunch, and dinner for 5 days. If you agree to participate you will be asked to complete a short questionneire with each meel for the 5 day period. This questionneire will ask you to rate how much you liked the meel items. At lunchtime you will also complete a questionneire to estimate how much you eat and drink. At breakfest and dinner, technicians will observe how much you eat and drink. Heale during the atudy will consist of hot B-ration items for breakfest and dinner and MRE's for lunch.

There ere no direct benefits to perticipents, however the information collected is very important for the Air Force's evaluation of B-ration consumption in a hot environment. There ere no risks associated with perticipation in this study.

If you have any questions about this study, feel free to sak or discuss them with the investigators at any time. If you wish to discuss the results of the study, you may do so but not until your participation is complete. If you volunteer for this study, we would like to be reasonably certain that you will complete it. But you have the right to withdraw from this study at any time without adverse consequences or prejudice.

All dets end information obtained about you as an individual will be considered priviledged and held in confidence. Complete confidentiality cannot be promised, particularly to subjects who are military members, because information bearing on your health may be required to be reported to appropriate medical or Command authorities, and applicable regulations note the possibility that the Food and Drug Administration and USAMRDC officials may inspect the records.

NAME	B-RATION and MRE V
NUMBER	

FINAL QUESTIONNAIRE

We would like to ask your opinions about the rations you ate this week. B-rations were served at breakfast and evening meals, and MREs were served at lunch. Your opinions will be very important in determining any changes that will be made in the rations, so please answer the questions thoughtfully.

- 1. Overall, did you get enough to eat this week or were you often hungry? Circle one number.

- Got enough to eat
 Was often hungry
 Was almost always hungry
- 2. Overall, did you get enough to drink this week or were you often thirsty?
 - 1. Got enough to drink
- 3. Was often thirsty
- Was sometimes thirsty
- 4. Was almost always thirsty

_¶

3. Please rate how SATISFIED or DISSATISFIED you were with each of the following aspects of the B-rations and MREs you ate this week. Circle one number for each aspect.

			NEITHER			
VERY	MODERATELY	SOMEWHAT	SATISFIED NOR		MODERATELY SATISFIED

APPENDIX H. WEATHER DATA: TEMPERATURES AND RELATIVE HUMIDITY DURING THE FIELD TEST

Average Temperatures ($^{\rm O}$ F) at Breakfast, Lunch and Dinner During the 5-Day Field Test.

DAY	<u>Breakfast</u>	Lunch	<u>Dinner</u>	Overall
1	76.3	87.0	90.3	84.3
2	77.7	89.5	94.0	85.7
3	77.5	93.5	92.5	87.8
4	78.7	89.3	92.7	86.9
5	78.3	NA	NA	NA
Overall	77.7	89.8	92.4	85.9

Average Temperature (°F) and Relative Humidity (%) Each Day During the 5-Day Field Test

DAY	Temperature	<u>High</u>	Low	Relative Humidity	<u>High</u>	Low
1	85.0	93	78	69.9	85	43
2	86.5	95	78	65.1	81	50
3	83.8	91	74	72.3	94	51
4	82.8	89	7 7	79.8	93	63
5	82.2	93	74	78.8	100	44
Overall	84.1	95	74	73.2	100	43

Average Outside Temperature ($^{\rm O}{\rm F}$) and Relative Humidity ($^{\rm L}$) During the 5-Day Field Test.

TIME OF THE DAY	TEMPERATURE	RELATIVE HUMIDITY
0100	85.8	73.2
